

Simple R Functions

Carlos Echeverri

January 26, 2018

1.

- (a) Write functions `tmpFn1` and `tmpFn2` such that if `xVec` is the vector (x_1, x_2, \dots, x_n) , then `tmpFn1(xVec)` returns vector $(x_1, x_2^2, \dots, x_n^n)$ and `tmpFn2(xVec)` returns the vector $(x_1, \frac{x_2^2}{2}, \dots, \frac{x_n^n}{n})$.

Here is `tmpFn1`

```
tmpFn1 <- function(xVec){  
  return(xVec^(1:length(xVec)))  
}
```

simple example

```
a <- c(2, 5, 3, 8, 2, 4)
```

```
b <- tmpFn1(a)
```

```
b
```

```
## [1]      2    25    27 4096    32 4096
```

and now `tmpFn2`

```
tmpFn2 <- function(xVec2){  
  
  n = length(xVec2)  
  
  return(xVec2^(1:n)/(1:n))  
}
```

```
c <- tmpFn2(a)
```

```
c
```

```
## [1]      2.0000    12.5000     9.0000 1024.0000     6.4000  682.6667
```

-
- (b) Now write a function `tmpFn3` which takes 2 arguments x and n where x is a single number and n is a strictly positive integer. The function should return the value of

$$1 + \frac{x}{1} + \frac{x^2}{2} + \frac{x^3}{3} + \dots + \frac{x^n}{n}$$

```
tmpFn3 <- function(x, n){  
  return(1 + sum((x^(1:n))/(1:n)))  
}
```

2. Write a function `tmpFn(xVec)` such that if `xVec` is the vector $x = (x_1, \dots, x_n)$ then `tmpFn(xVec)` returns the vector of moving averages:

$$\frac{x_1 + x_2 + x_3}{3}, \frac{x_2 + x_3 + x_4}{3}, \dots, \frac{x_{n-2} + x_{n-1} + x_n}{3}$$

```
tmpFn <- function(xVec){
  length(xVec) -> n
  return((xVec[1:(n-2)]+xVec[2:(n-1)]+xVec[3:n])/3)
}
```

Try out your function. `tmpFn(c(1:5,6:1))`

```
tmpFn( c(1:5,6:1) )

## [1] 2.000000 3.000000 4.000000 5.000000 5.333333 5.000000 4.000000 3.000000
## [9] 2.000000
```

3. Consider the continuous function

$$f(x) = \begin{cases} x^2 + 2x + 3 & \text{if } x < 0 \\ x + 3 & \text{if } 0 \leq x < 2 \\ x^2 + 4x - 7 & \text{if } 2 \leq x \end{cases}$$

Write a function `tmpFn` which takes a single argument `xVec`. the function should return the vector the values of the function $f(x)$ evaluated at the values in `xVec`.

```
tmpFn <- function(x){
  ifelse(x < 0, x^2 + 2*x + 3, ifelse(x < 2, x+3, x^2 + 4*x - 7))
}
```

Hence plot the function $f(x)$ for $-3 < x < 3$.

```
x <- seq(-3,3, by=.1)
y <- tmpFn(x)
plot(x = x, y = y)
```

4. Write a function which takes a single argument which is a matrix. The function should return a matrix which is the same as the function argument but every odd number is doubled.

Hence the result of using the function on the matrix

$$\begin{bmatrix} 1 & 1 & 3 \\ 5 & 2 & 6 \\ -2 & -1 & -3 \end{bmatrix}$$

should be:

$$\begin{bmatrix} 2 & 2 & 6 \\ 10 & 2 & 6 \\ -2 & -2 & -6 \end{bmatrix}$$

```
double_odd <- function(x){
  ifelse(abs(x)%2 == 0, x, 2*x)
}
```

```
M <- matrix(c(1,1,3,5,2,6,-2,-1,-3), nrow = 3,byrow = T)
M
```

```
##      [,1] [,2] [,3]
## [1,]    1    1    3
## [2,]    5    2    6
## [3,]   -2   -1   -3
```

```
double_odd(M)
```

```
##      [,1] [,2] [,3]
## [1,]    2    2    6
## [2,]   10    2    6
```

```
## [3,] -2 -2 -6
```

5. Write a function which takes 2 arguments n and k which are positive integers. It should return the $n \times n$ matrix:

$$\begin{bmatrix} k & 1 & 0 & 0 & \cdots & 0 & 0 \\ 1 & k & 1 & 0 & \cdots & 0 & 0 \\ 0 & 1 & k & 1 & \cdots & 0 & 0 \\ 0 & 0 & 1 & k & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & k & 1 \\ 0 & 0 & 0 & 0 & \cdots & 1 & k \end{bmatrix}$$

```
tmpFn4 <- function(n, k){
  M <- matrix(rep(0, times = n^2), nrow = n)
  for (i in 1:n){
    if(i==1){
      M[i,i]= k; M[i+1,i]= 1;
    } else if (i==n){
      M[i,i]= k; M[i-1,i]= 1;
    } else{
      M[i,i]= k; M[i-1,i]= 1; M[i+1,i]= 1;
    }
  }
  return(M)
}
```

```
tmpFn4(5, 2)
```

```
##      [,1] [,2] [,3] [,4] [,5]
## [1,]    2    1    0    0    0
## [2,]    1    2    1    0    0
## [3,]    0    1    2    1    0
## [4,]    0    0    1    2    1
## [5,]    0    0    0    1    2
```

6. Suppose an angle α is given as a positive real number of degrees.

If $0 \leq \alpha < 90$ then it is quadrant 1. If $90 \leq \alpha < 180$ then it is quadrant 2.

if $180 \leq \alpha < 270$ then it is quadrant 3. if $270 \leq \alpha < 360$ then it is quadrant 4.

if $360 \leq \alpha < 450$ then it is quadrant 1.

And so on ...

Write a function `quadrant(alpha)` which returns the quadrant of the angle α .

```
quadrant <- function(alpha){
  return(1 + (alpha %% 360) %/% 90)
}
```

7.

(a) Zeller's congruence is the formula:

$$f = ([2.6m - 0.2] + k + y + [y/4] + [c/4] - 2c) \bmod 7$$

where $[x]$ denotes the integer part of x ; for example $[7.5] = 7$.

Zeller's congruence returns the day of the week f given:

k = the day of the month

y = the year in the century

c = the first 2 digits of the year (the century number)

m = the month number (where January is month 11 of the preceding year, February is month 12 of the preceding year, March is month 1, etc.)

For example, the date 21/07/1963 has $m = 5, k = 21, c = 19, y = 63$;

the date 21/2/63 has $m = 12, k = 21, c = 19, \text{and } y = 62$.

Write a function `weekday(day, month, year)` which returns the day of the week when given the numerical inputs of the day, month and year.

Note that the value of 1 for f denotes Sunday, 2 denotes Monday, etc.

```
weekday <- function(day, month, year){
  k = day
  if (month <= 2){
    m = month + 10; year = year - 1
  } else{
    m = month
  }
  c = year %/% 100
  y = year %% 100
  f = ((2.6*m-0.2)%/%1 + k + y + y%/%4 + c%/%4 - 2*c)%%7
  c("Sunday", "Monday", "Tuesday", "Wednesday", "Thursday", "Friday", "Saturday")[1+f%7]
}
```

(b) Does your function work if the input parameters day, month, and year are vectors with the same length and valid entries?

No, it only works one date at a time, for example:

```
a=weekday(4,2,2018)
a
## [1] "Sunday"
```
